

# Metal Industry Indicators

## Indicators of Domestic Primary Metals, Steel, Aluminum, and Copper Activity

---

July 2009

---

The primary metals leading index registered a hefty increase in June, and its 6-month smoothed growth rate climbed substantially higher. While the growth rate remains in negative territory and is not yet indicating an end to the cyclical decline in the primary metals industry, it is suggesting that the rate of decline could slow in the near future. The metals price leading index growth rate has moved above the threshold that denotes an increase in metals price growth, however recovery from the U.S. recession and the global economic slowdown may be too slow to sustain significant metals price growth in the near term.

The primary aluminum and the aluminum mill products indexes are suspended because of discontinued availability of industry-specific historical data. The USGS will continue to calculate the steel and copper composite indexes.

The **primary metals leading index** increased 2.5% in June to 126.6 from a revised 123.5 in May. The index's 6-month smoothed growth rate, a compound annual rate that measures the near-term trend increased to -7.1% from a revised -14.1% in May. A growth rate above +1.0% is usually a sign of an upward near-term trend for future metals activity, while a growth rate below -1.0% indicates a downward trend. For an explanation of these indexes and a definition of the primary metals industry, [see page 10](#).

Four of the index's eight components were available in time for the June index calculation. Three of these components increased, with the JOC-ECRI metals price index growth rate making the largest positive contribution, 1.8 percentage points, to the net increase in the leading index. While this component is still negative, it has steadily risen since the start of the year. The Institute for Supply Management's PMI also has increased since the beginning of the year; however, it has yet to move above the threshold that denotes an increase in U.S. manufacturing activity. It contributed 0.6 percentage points to the leading index. The stock price index combining construction and farm machinery companies and industrial machinery companies contributed 0.3 percentage points to the leading index. In contrast, a slightly shorter average workweek in primary metals establishments in June held the leading index back by 0.2 percentage points. The average workweek has shortened by nearly 3 hours over the last year. The primary metals leading index will likely be revised next month when the remaining four components become available.

The primary metals leading index has increased 3 consecutive months, and while its growth rate has steadily risen from a record low in March, it is still below the threshold that signals an upturn

in metals activity growth. Economic conditions in the United States and other countries will have to improve to generate major metals demand. A deceleration in the decline in activity growth in the U.S. primary metals industry is most likely in the near future.

The **steel leading index** increased 1.8% in May, the latest month for which it is available, to 101.2 from a revised 99.4 in April, and its 6-month smoothed growth rate increased to -10.0% from a revised -15.3% in April. Eight of its nine indicators increased, but it was improvement in the average workweek in iron and steel plants that made the largest contribution to the steel leading index. Increases in the PMI and the S&P stock price index for steel companies also made sizable contributions. Pullbacks in household appliance shipments offset some of the gains in other indicators. The steel leading index growth rate indicates further declines in U.S. steel industry activity in the near term.

The **copper leading index** remained at its revised April level of 105.7 in May, and its 6-month smoothed growth rate increased to -13.5% from a revised -15.6%. Movement among its indicators was mixed, but the sharp increase in the S&P stock price index for building products companies made the largest positive contribution to the leading index. On the other hand, the fewest average overtime hours in copper rolling, drawing, extruding, and alloying plants on record offset advances in other indicators. The copper leading index growth rate is still indicating decreases in near-term domestic copper activity.

### Metals Price Growth Precarious

The **metals price leading index** increased 2.2 % to 106.4 in May, the latest month for which it is available, from a revised

104.1 in April. Its 6-month smoothed growth rate surged to 7.0% from a revised 2.4% in April. Two of its three available indicators increased. However, it was the rising growth rate of the trade-weighted average exchange value of other major currencies against the U.S. dollar that made the largest contribution, 2.2 percentage points, to the net increase in the leading index. A wider yield spread between the U.S. 10-year Treasury Note and the federal funds rate contributed 0.5 percentage points. In contrast, the falling growth rate of the inflation-adjusted value of new orders for U.S. nonferrous metal products pulled the leading index down 0.5 percentage points. The fourth component, the growth rate of the Economic Cycle Research Institute's (ECRI) 19-Country Long Leading Index, is only available through April. It increased for the fifth consecutive month, and while still in negative territory, it is close to moving above the -1.0% threshold that would no longer signal a decline in economic activity for most major industrialized countries. This index signals changes in the growth of economic activity about 5 months in advance. The metals price leading index signals major

changes in the growth rate of nonferrous metals prices an average of 8 months in advance.

The growth rate of the inflation-adjusted value of U.S. nonferrous metal products inventories, which is an indicator of supply and usually moves inversely with the price of metals, decreased in May and has fallen every month this year. The declining metal inventories growth rate and the robust metals price leading index growth rate, spurred on by the weak dollar, would normally indicate strong metals price growth. However, uncertainty over how long the U.S. recession will last and when the slowdowns in many global economies will end puts downward pressure on metals price growth.

The business cycle and inventories are only two factors in metal price determination. Other factors that affect prices include changes in metals production, speculation, strategic stockpiling, foreign exchange rates, geopolitical instability, and production costs.

**Note:** The components of the Leading Index of Metal Prices are the spread between the U.S. 10-year Treasury Note and the federal funds rate, and the 6-month smoothed growth rates of the deflated value of new orders for nonferrous metal products, the Economic Cycle Research Institute's 19-Country Long Leading Index, and the reciprocal of the trade-weighted average exchange value of the U.S. dollar against other major currencies. The Metal Industry Indicators (MII) Nonferrous Metals Price Index measures changes in end-of-the-month prices for primary aluminum, copper, lead, and zinc traded on the London Metal Exchange (LME). The steel scrap price used is the price of No. 1 heavy melting. Inventories consist of the deflated value of finished goods, work in progress, and raw materials for U.S.-produced nonferrous metal products (NAICS 3313, 3314, & 335929). Six-month smoothed growth rates are based on the ratio of the current month's index or price to its average over the preceding 12 months, expressed at a compound annual rate.

## Explanation

Each month, the U.S. Geological Survey tracks the effects of the business cycle on five U.S. metal industries by calculating and publishing composite indexes of leading and coincident indicators. Wesley Mitchell and Arthur Burns originated the cyclical-indicators approach for the economy as a whole at the National Bureau of Economic Research in the mid-1930s. Over subsequent decades this approach was developed and refined, mostly at the National Bureau, under the leadership of Geoffrey H. Moore.<sup>1</sup>

A business cycle can briefly be described as growth in the level of economic activity followed by a decline succeeded by further growth. These alternating periods of growth and decline do not occur at regular intervals. Composite indexes, however, can help determine when highs and lows in the cycle might occur. A composite index combines cyclical indicators of diverse economic activity into one index, giving decision makers and economists a single measure of how changes in the business cycle are affecting economic activity.

The indicators in the metal industry leading indexes historically give signals several months in advance of major changes in a coincident index, a measure of current metal industry activity. Indicators that make up the leading indexes are, for the most part, measures of anticipations or new commitments to various economic activities that can affect the metal industries in the months ahead.

Composite coincident indexes for the metal industries consist of indicators for production, shipments, and total employee hours worked. As such, the coincident indexes can be regarded as measures of the economic health of the metal industries.

The metal industry coincident indexes reflect industry activity classified by the U.S. Standard Industrial Classification (SIC) and the North American Industry Classification System (NAICS). Of the five metal industries, primary metals (NAICS 331) is the broadest, containing 25 different metal processing industries. Steel, aluminum, and copper are specific industries within the primary metals group.

The SIC was the main vehicle used by the U.S. Government and others in reporting industry economic statistics throughout most of the last century. Starting with the 1997 U.S. Economic Census, the U.S. Government began using the NAICS, which classifies economic data for industries in Canada, Mexico, and the United States. In general, metal industry indexes starting in 1997 begin to reflect the NAICS classification, while indexes for earlier years follow the SIC. Hence, composite indexes from 1997 forward are not entirely consistent with those of earlier years.

The largest change to primary metals because of the NAICS deals with other communication and energy wire manufacturing (NAICS 335929). Under NAICS, this manufacturing has been removed from primary metals and added to electrical equipment, appliance, and component manufacturing. Because monthly shipments and new orders for this wire are not available, the USGS is estimating their values from 1997 onward and adding them to the appropriate metal industry indicators and indexes to maintain consistency.

---

<sup>1</sup>Business Cycle Indicators, A monthly report from The Conference Board (March 1996).

There are other small changes to the primary metals industry because of the switch to the NAICS. Coke oven activity not done by steel mills, for example, is removed and alumina refining, a part of industrial inorganic chemical manufacturing under the SIC, is added. Since the historic trends of the composite indexes are not affected by these small changes, the USGS is not making specific adjustments to the indexes for them for the periods before and after 1997.

The metal industry leading indexes turn before their respective coincident indexes an average of 8 months for primary metals and 7 months for steel and copper. The average lead time for the primary aluminum leading index is 6 to 8 months, and the average lead time for the aluminum mill products leading index is 6 months.

The leading index of metal prices, also published in the *Metal Industry Indicators*, is designed to signal changes in a composite index of prices for primary aluminum, copper, lead, and zinc traded on the London Metal Exchange. On average, this leading index indicates significant changes in price growth about 8 months in advance.

The growth rate used in the *Metal Industry Indicators* is a 6-month smoothed growth rate at a compound annual rate, calculated from a moving average. Moving averages smooth fluctuations in data over time so that trends can be observed. The 6-month smoothed growth rate is based upon the ratio of the latest monthly value to the preceding 12-month moving average.

$$\left[ \left( \frac{\text{current value}}{\text{preceding 12-month moving average}} \right)^{\frac{12}{6.5}} - 1.0 \right] * 100$$

Because the interval between midpoints of the current month and the preceding 12 months is 6.5 months, the ratio is raised to the 12/6.5 power to derive a compound annual rate.

The growth rates measure the near-term industry trends. They, along with other information about the metal industries and the world economy, are the main tools used to determine the outlook of the industries. A 6-month smoothed growth rate above +1.0% usually means increasing growth; a rate below -1.0% usually means declining growth.

**The next update for these indexes is scheduled for release on the World Wide Web at 10:00 a.m. EDT, Friday, August 21. The address for *Metal Industry Indicators* on the World Wide Web is: <http://minerals.usgs.gov/minerals/pubs/mii/>**

The *Metal Industry Indicators* is produced at the U.S. Geological Survey by the Minerals Information Team. The report is prepared by Gail James (703-648-4915; e-mail: [gjames@usgs.gov](mailto:gjames@usgs.gov)) and Ken Beckman (703-648-4916; e-mail: [kbeckman@usgs.gov](mailto:kbeckman@usgs.gov)). The former Center for International Business Cycle Research, under the direction of Dr. Geoffrey H. Moore, and the former U.S. Bureau of Mines developed the metal industry leading and coincident indexes in the early 1990s. Customers can send mail concerning the *Metal Industry Indicators* to the following address:
